

The Responsiveness problem (and solution: Ajax)

Reactive Web Design

Reactive Web Design: a set of techniques that can be used to build sites that always feel fast and responsive to user input regardless of the network speed or latency.

Reactive programming is programming with **asynchronous data streams**.

Responsive Web Design

Responsive design is an approach to **web** page creation that makes use of flexible layouts, flexible images and cascading style sheet media queries. The goal of **responsive design** is to build **web** pages that detect the visitor's screen size and orientation and change the layout accordingly.

The form nightmare...

⁶Ajax !

- not a technology in itself: it is a term coined in 2005 by Jesse James Garrett: “Asynchronous JavaScript + XML”.
- new development technique
 - ◆ blur the line between web-based and desktop applications.
 - ◆ rich, highly responsive and interactive interfaces

Ajax was born as:

- dynamic presentation based on **XHTML + CSS**;
- dynamic display and interaction using **Document Object Model**;
- data exchange and manipulation using **XML e XSLT**;
- asynchronous data fetching using **XMLHttpRequest**;
- **JavaScript** as glue.

How does Ajax work?

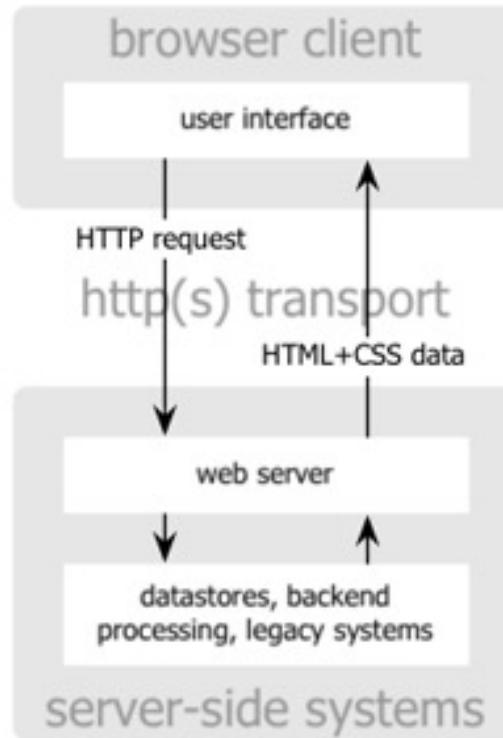

- The core idea behind AJAX is to make the communication with the server asynchronous, so that data is transferred and processed in the background.
- As a result the user can continue working on the other parts of the page without interruption.
- In an AJAX-enabled application only the relevant page elements are updated, only when this is necessary.

The paradigms

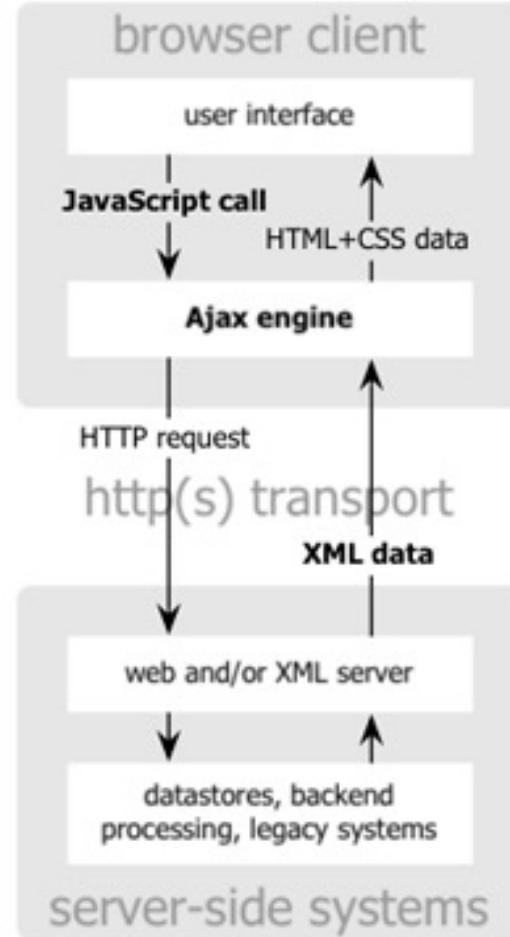

1.0

classic
web application model

*Pictures after
Jesse James Garrett*

2.0

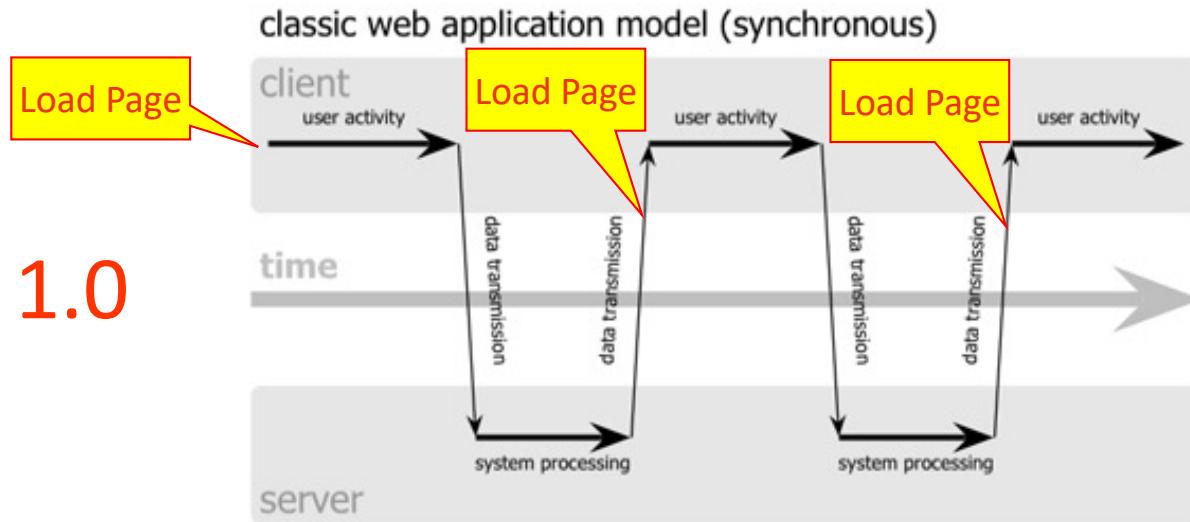

Ajax
web application model

The models

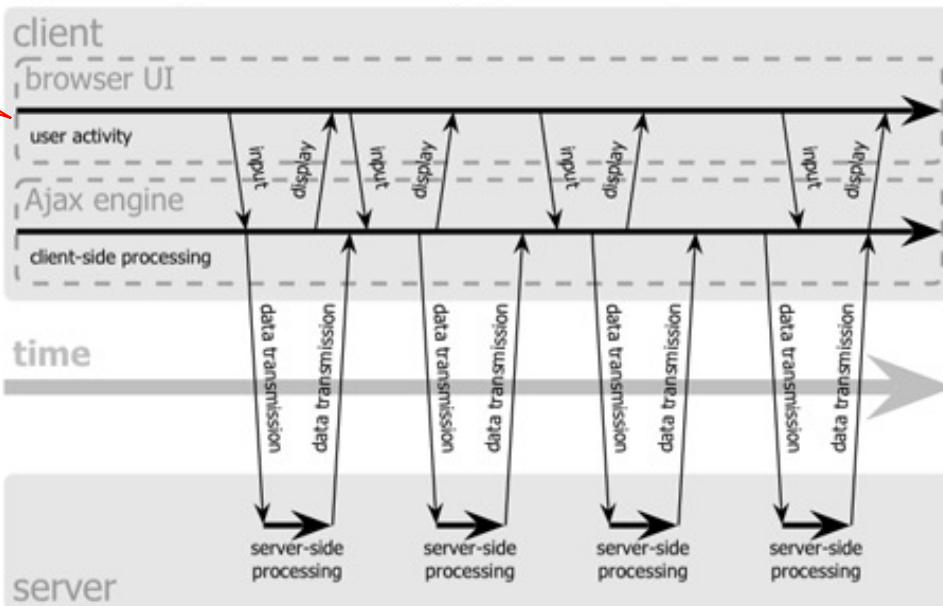

1.0

2.0

Ajax web application model (asynchronous)

*Pictures after
Jesse James Garrett*

The heart and history of Ajax

- First used after Microsoft implemented Microsoft **XMLHTTP** COM object that was part of The Microsoft® XML Parser (IE 5.1)
 - ◆ Similarly supported by a Mozilla Javascript object **XMLHttpRequest** (*Mozilla 1.0, Firefox, Safari 1.2 etc.*)
 - ◆ Massively used by Google

Other labels for the same technology were **Load on Demand**, **Asynchronous Requests**, **Callbacks**, **Out-of-band Calls**, etc.

¹¹Ajax code

```
if (window.XMLHttpRequest) { // Mozilla, Safari, ...
    http_request = new XMLHttpRequest();
} else if (window.ActiveXObject) { // IE
    http_request = new ActiveXObject("Microsoft.XMLHTTP");
}
```

¹²Ajax - advantages

- ◆ Rich applications in browsers
- ◆ No issues with installation
- ◆ Built on existing infrastructure (TCP/IP, SSL, HTTP, XML...)

23	1.3.1.4 Junior Faculty in Poznan Poland	Per rr	3	1000	3,000.00		

¹⁴Ajax - advantages

- ◆ Better Performance and Efficiency
 - small amount of data transferred from the server. Beneficial for **data-intensive applications as well as for low-bandwidth networks.**
- ◆ More Responsive Interfaces
 - the improved performance give the feeling that updates are happening instantly. AJAX web applications appear to behave much like their desktop counterparts.
- ◆ Reduced or Eliminated "Waiting" Time
 - only the relevant page elements are updated, with the rest of the page remaining unchanged. This decreases the idle waiting time.
- ◆ Increased Usability
 - ◆ Users can work with the rest of the page while data is being transferred in the background.

XMLHttpRequest

```
function loadDoc() {  
    var xhttp = new XMLHttpRequest();  
    xhttp.onreadystatechange = function() {  
        if (this.readyState == 4 && this.status == 200) {  
            document.getElementById("demo").innerHTML =  
                this.responseText;  
        }  
    };  
    xhttp.open("GET", "ajax_info.txt", true);  
    xhttp.send();  
}
```

Asynchronous
Programming!

XMLHttpRequest – Getting static resources

```
function loadDoc() {  
    var xhttp = new XMLHttpRequest();  
    xhttp.onreadystatechange = function() {  
        if (this.readyState == 4 && this.status == 200) {  
            document.getElementById("demo").innerHTML =  
                this.responseText;  
        }  
    };  
    xhttp.open("GET", "ajax_info.txt", true);  
    xhttp.send();  
}
```

Getting dynamic resources with GET

```
function loadDoc() {  
    var xhttp = new XMLHttpRequest();  
    xhttp.onreadystatechange = function() {  
        if (this.readyState == 4 && this.status == 200) {  
            document.getElementById("demo").innerHTML =  
                this.responseText;  
        }  
    };  
    xhttp.open("GET", "myservlet?param1=27", true);  
    xhttp.send();  
}
```

Note: if you want to avoid getting cashed results, add a fake parameter with the current time, e.g.

```
xhttp.open("GET", url + ((/\?/).test(url) ? "&" : "?") + (new Date()).getTime());
```

See https://www.w3schools.com/jsref/jsref_regexp_test.asp to understand the code above

Getting dynamic resources with POST

```
function loadDoc() {  
    var xhttp = new XMLHttpRequest();  
    xhttp.onreadystatechange = function() {  
        if (this.readyState == 4 && this.status == 200) {  
            document.getElementById("demo").innerHTML =  
                this.responseText;  
        }  
    };  
    xhttp.open("POST", "ajax_info.txt", true);  
    xhttp.setRequestHeader("Content-type",  
        "application/x-www-form-urlencoded");  
    xhttp.send("nome=Dorothea&lname=Wierer");  
}
```

- 1) add an HTTP header with setRequestHeader().
- 2) Specify the data you want to send in the send() method

XMLHttpRequest methods

<code>new XMLHttpRequest()</code>	Creates a new XMLHttpRequest object
<code>abort()</code>	Cancels the current request
<code>getAllResponseHeaders()</code>	Returns header information
<code>getResponseHeader()</code>	Returns specific header information
<code>open(<i>method</i>, <i>url</i>, <i>async</i>, <i>user</i>, <i>psw</i>)</code>	<p>Specifies the request</p> <p><i>method</i>: the request type GET or POST <i>url</i>: the file location <i>async</i>: true (asynchronous) or false (synchronous) <i>user</i>: optional user name <i>psw</i>: optional password</p>
<code>send()</code>	Sends the request to the server Used for GET requests
<code>send(<i>string</i>)</code>	Sends the request to the server. Used for POST requests
<code>setRequestHeader()</code>	Adds a label/value pair to the header to be sent

XMLHttpRequest properties

Property	Description
onreadystatechange	Defines a function to be called when the readyState property changes
readyState	Holds the status of the XMLHttpRequest. 0: request not initialized 1: server connection established 2: request received 3: processing request 4: request finished and response is ready
responseText	Returns the response data as a string
responseXML	Returns the response data as XML data
status	Returns the HTTP status-number of a request, e.g. 200: "OK" 403: "Forbidden" 404: "Not Found"
statusText	Returns the status-text (e.g. "OK" or "Not Found")

²¹

And make sure that you...

- **Preserve the Normal Page Lifecycle** – as much as possible!
- **Reflect Control State on the Server** – in real-life scenarios there is no use of simply rendering controls on the page.
- **Support Cross-Browser usage** – there are different implementation of the XMLHttpRequest object. You should make sure that all AJAX components you choose operate properly on various browsers and platforms.
- **Ensure proper Operation when Cookies are Disabled** – support cookieless sessions.

²²

And make sure that you...

- ◆ **Give visual feedback** - When a user clicks on something in the AJAX user interface, they need immediate visual feedback
- ◆ **Keep the Back button** – make sure that the Back button in your application functions on every page of the site.
- ◆ **Use links for navigation** – avoid the temptation to use links as an interface on your AJAX application to change the state of your application. Users have been trained over many years to expect a link to “take” them somewhere, so give them what they expect.
- ◆ **Use human-readable links** – people like to pass the addresses of useful web pages to each other. Make sure your application supports URLs that people can share easily, so not too long or complex.

And make sure that you...

- ◆ **Don't bloat the code** – make sure that your application uses as little client-side scripting as possible. This reduces download time for the page and also reduces the processor requirements on the client browser, so results in a faster browser experience.
- ◆ **Follow UI conventions** – AJAX is a world of possibilities, but when it comes to user interface the best is invariably the familiar. If you're creating a user interface for a specific feature, the place to start is by replicating an existing successful interface and looking at what your clients expect. Also remember that although it may be cool to implement drag-and-drop, few people may realize the interface relies on it.
- ◆ **Don't scroll** – users like to feel in control, so if they have moved the scrollbar to a specific place, don't move the page somewhere else.
- ◆ **Reduce page loads** – do as much as you can to reduce the number of page loads the user has to do to achieve their goal.

Cross Origin

For security reasons, browsers restrict cross-origin HTTP requests **initiated from scripts**.

CORS - Cross-Origin Resource Sharing

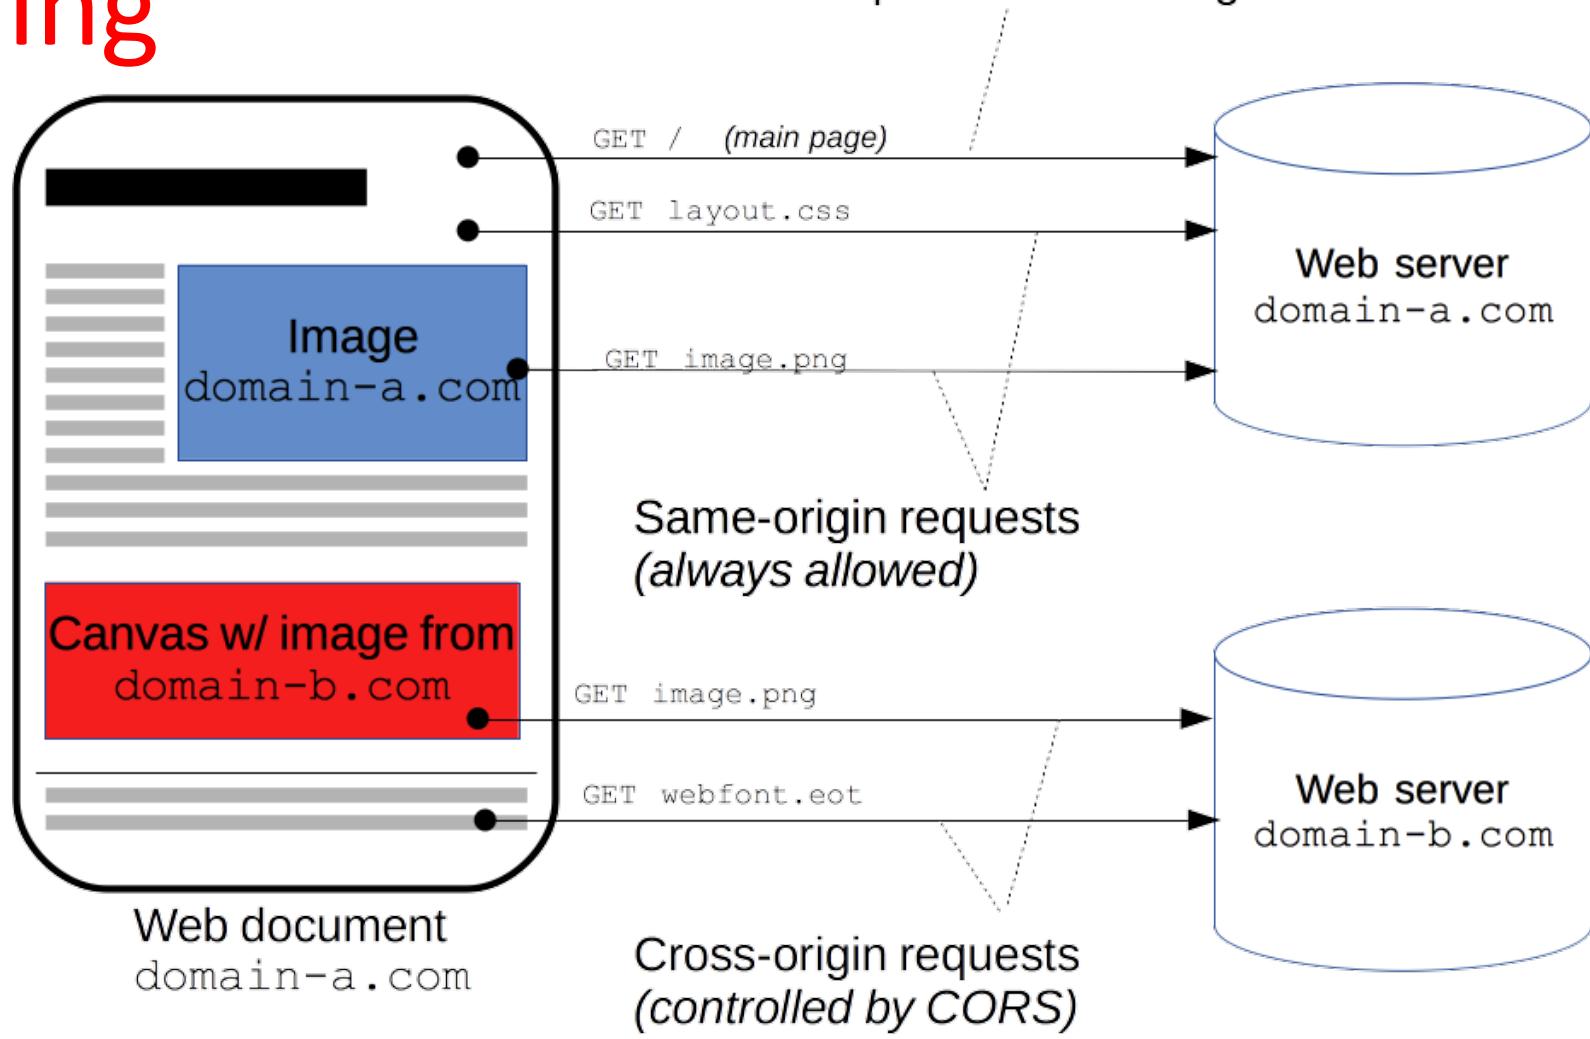

immagine da <https://developer.mozilla.org/en-US/docs/Web/HTTP/CORS>

CORS

- **Cross-site XMLHttpRequest**
- Modern browsers support cross-site requests by implementing the **Cross-Origin Resource Sharing** (CORS) standard. As long as the server is configured to allow requests from your web application's origin, XMLHttpRequest will work. Otherwise, an `INVALID_ACCESS_ERR` exception is thrown.
- CORS failures result in errors, but for security reasons, specifics about the error *are not available to JavaScript*. All the code knows is that an error occurred.

CORS

```
const xhr = new XMLHttpRequest();
const url = 'https://bar.other/resources/public-data/';
xhr.open('GET', url);
xhr.onreadystatechange = someHandler;
xhr.send();
```

What the browser will send to the server:

GET /resources/public-data/ HTTP/1.1

Host: bar.other

User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10.14; rv:71.0) Gecko/20100101 Firefox/71.0

**Accept: text/html,application/xhtml+xml,
application/xml;**

Accept-Language: en-us,en;q=0.5

Accept-Encoding: gzip,deflate

Connection: keep-alive

Origin: https://foo.example

How the server will respond:

CORS

HTTP/1.1 200 OK

Date: Mon, 01 Dec 2008 00:23:53 GMT

Server: Apache/2

Access-Control-Allow-Origin: *

Keep-Alive: timeout=2, max=100

Connection: Keep-Alive

Transfer-Encoding: chunked

Content-Type: application/xml

[...XML Data...]

Alternatives:

Access-Control-Allow-Origin: https://foo.example

For more detail, see <https://developer.mozilla.org/en-US/docs/Web/HTTP/CORS>

Adding CORS to Apache

- To add the CORS authorization to the header using Apache, simply add the following line inside either the `<Directory>`, `<Location>`, `<Files>` or `<VirtualHost>` sections of your server config (usually located in a `*.conf` file, such as `httpd.conf` or `apache.conf`), or within a `.htaccess` file:

```
Header set Access-Control-Allow-Origin "*"
```
